CONTENTS

Contributors	ix
Figures	xv
Tables	xvii
Introduction	1
Archaeology, if you like	2
People, landscapes and lifeways	3
A biographical sketch of Charly French, geoarchaeologist	5
Some memories from Helen Lewis	6
A gift to archaeology, by Federica Sulas	8
Through the looking glass, by Manuel Arroyo-Kalin	10
Publications and reports by Charly French	15
Personal accounts	27
Picking my way along the catena path with Charly (Kasia Gdaniec)	27
Canadian connections: Charly's early days digging in the East Anglian Fens (Francis Pryor)	30
Developing geoarchaeology: contextual analyses and the urgency of the sustainability agenda (Wendy Matthews)	32
An archaeology of the Anthropocene: uncovering lost landscapes with Charly French (Nicole Boivin)	37
Firmly on the ground: science and a three-dimensional past (Martin Jones)	41
Geoarchaeology: reflections on progress and prospects (Martin Bell)	43
Part I Archaeology, if you like	51
Chapter 1 Practising geoarchaeology: on land, underwater, online	53
FRASER STURT	
Geoarchaeology?	53
Practising geoarchaeology: fieldwork	58
Narrative and knowledge	59
Practising geoarchaeology: teaching, learning and supporting	59
Conclusions	60
Chapter 2 Why do we see what we see where we see it? Geomorphological controls on archaeological narratives across space and time	61
ROBYN H. INGLIS	
Shaping the surface record	62
Shaping deep sequences	68
Conclusions	71
Chapter 3 Landscapes of scale or scales of landscape: patterns of land use and landscape	73
MICHAEL J. ALLEN	
Land-use patterns (a proxy for human activity)	74
Patterns of land use	78
All change: a new geoarchaeology and palaeo-environment to consider	84
Conclusions: concepts and communicating patterns of land use	86
Postscript	87

<i>Chapter 4</i>	Geoarchaeology in fluvial landscapes	89
	ANDREA L. BALBO	
	Four hundred feet under. The flooded Raša-Boljunščica River system and the spread of anatomically modern humans to Mediterranean Europe	89
	After the ice. Northern incursions along the Rena River at the beginning of the Holocene following the melting of the Scandinavian Ice Sheet	91
	Down the river. Agriculture and trade in the dynamic floodplain of Basses Terres, Rhône River during late antiquity	92
	Streamlined water networks. Spring capture, irrigation and terracing in the Valley of Ricote, al-Andalus, Spain	92
	Boom and burst. Terraced agriculture in Minorca through the Medieval Climatic Anomaly and the Little Ice Age	94
	What's next? Trends and potential for geoarchaeology in fluvial landscapes, and beyond	94
<i>Chapter 5</i>	Challenges of geoarchaeology in wetland environments	97
	CRISTIANO NICOSIA	
	Wetland sediments	98
	Wetland sediments in archaeological contexts	100
	Conclusions	105
<i>Chapter 6</i>	Soil pollen analysis: a waning science?	107
	ROB SCAIFE	
	Introduction: a background to soil pollen analysis	107
	Taphonomy of pollen in soil	108
	The pollen method	111
	Research archaeological and experimental studies	113
	Conclusion	114
<i>Chapter 7</i>	Making thin sections for geoarchaeology	117
	TONKO RAJKOVACA	
	Soils and micromorphology in archaeology	118
	Sampling soils and sediments	118
	Thin section making	120
	Sawing of samples	123
Part II	Peoples, landscapes and lifeways	127
<i>Chapter 8</i>	Modelling, mimicking and fighting waters: Lower River Great Ouse and Ouse Washlands investigations	129
	CHRISTOPHER EVANS	
	Tracing waters (and islands) – fathoming lands	129
	Bringing the Fens to Cambridge – the Ouse Tidal Model	134
	The 'Big Straight' and the Hovertrain	137
	Flat earths – engineerings and follies	140
	Multiple strands and reclamations	141
<i>Chapter 9</i>	Speculations on farming development during the early Iron Age of southern Norway (500 BC–AD 550), focusing on the Dobbeltspor Dilling Project	145
	RICHARD I. MACPHAIL, JOHAN LINDERHOLM & LARS ERIK GJERPE	
	Archaeological context of settlement and farming in Norway, with special attention to Iron Age southern Norway	146
	The Dilling site	147
	Methods	149
	Results	149
	Discussion and conclusions	153

<i>Chapter 10</i>	A geoarchaeological agenda for Tyrrhenian central Italy	157
	SIMON STODDART & CAROLINE MALONE	
	The state of geoarchaeology in central Tyrrhenian Italy	160
	Studies of urban centres	163
	A model for Tyrrhenian central Italy	163
	Testing the model	163
	Conclusions	164
<i>Chapter 11</i>	Landscape sequences and Iron Age settlement in southern Africa: managing soils and water in the Greater Mapungubwe landscape	167
	FEDERICA SULAS, BONGUMENZI NXUMALO & INNOCENT PIKIRAYI	
	Mapungubwe landscapes, ecologies, and cultures	169
	Geoarchaeological work	170
	Characterizing the Mapungubwe landscapes through time	172
	Building local landscape sequences for Mapungubwe	179
	Discussion and conclusions	180
<i>Chapter 12</i>	Tracking down the house: the contribution of micro-geo-ethnoarchaeology to the study of degraded houses in arid, temperate and humid tropical environments	183
	DAVID E. FRIESEM	
	Micro-geo-ethnoarchaeology	183
	Case study 1 – arid environment	184
	Case study 2 – temperate environment	186
	Case study 3 – humid tropical environment	188
	Discussion	190
<i>Chapter 13</i>	Soil micromorphological observations of construction techniques at Százhalombatta-Földvár Bronze Age tell settlement, Hungary	193
	GABRIELLA KOVÁCS & MAGDOLNA VICZE	
	Methods	195
	Results and discussion	195
	Conclusions	206
<i>Chapter 14</i>	Cursus complexity: results of geophysical survey on the Dorset Cursus, Cranborne Chase, Dorset	209
	MARTIN GREEN, MICHAEL GILL & ROY LOVEDAY	
	Back to the field – 2018 onwards	209
	The geophysical survey in Cursus and Fir Tree Fields	211
	Discussion (Roy Loveday)	213
	Implications (Roy Loveday)	216
<i>Chapter 15</i>	Three wettings and a funeral: monument construction, land use history, and preservation at Skelhøj and Tobøl I round barrows, Denmark	219
	HELEN LEWIS & ANN-MARIA HART	
	Methods and sites	221
	Results	222
	Comparing preservation environments	228
	Discussion	231
	Conclusions	234
	References	235

CONTRIBUTORS

MICHAEL J. ALLEN

Allen Environmental Archaeology, Redroof, Green Road, Codford, Wiltshire, BA12 0NW, UK

Email: aea.escargots@gmail.com

Mike's (BSc, PhD, MCIfA, FLS, FSA) research and geoarchaeological interest was originally based around the analysis of colluvium and land snails, including in the South Downs, Dorchester, Cranborne Chase, Stonehenge and Avebury in particular; these were the subject of both his undergraduate and PhD research. He has combined a career dominated by commercial archaeology with involvement in university research projects and as a staff lecturer at Sussex, Bournemouth and Oxford Universities. He was Environmental Manager at Wessex Archaeology for twenty years and for fifteen years has run his own geoarchaeological consultancy from a purpose-built bespoke lab, where he is involved in research designs and coordination of environmental archaeology from fieldwork to publication. Projects have been as diverse as intertidal zone research and Maltese prehistoric temples. His interests now lie principally in landscape archaeology and the development and creation of landscapes through prehistoric human intervention. He has worked with – and still is working with – Charly French in Cranborne Chase, the Stonehenge Riverside Project, and both recent Avebury landscape projects. He is vice-president of the Conchological Society, and as founding editor of the Prehistoric Society Research Papers has seen ten peer-reviewed volumes through to publication.

MANUEL ARROYO-KALIN

Institute of Archaeology, University College London, 31–34 Gordon Sq., London WC1H 0PY, UK
Email: m.arroyo-kalin@ucl.ac.uk

Manuel is Associate Professor of Geoarchaeology at the Institute of Archaeology, UCL. He is interested in the Anthropocene, Human Niche Construction, and Historical Ecology and uses earth science methods, including soil micromorphological analysis, to study past anthropic landscape modification and anthropogenic soil formation. His main research focus is the pre-Colonial human landscape history of tropical lowland South America, particularly the Amazon basin, where he is engaged in the long-term comparative study of Amazonian Dark Earths. He has also been involved in geoarchaeological studies in other world regions and published on the archaeology and palaeodemography of the Amazon basin. In recent years he has coordinated an intercultural and interdisciplinary research project focused on the northwest Amazon region.

ANDREA L. BALBO.

Platform Anthropocene, 160 Riverside Blvd, 30E - 10069 New York, NY, USA

Email: andrea.balbo@planthro.org

Following his PhD at the University of Cambridge (2008), Andrea conducted geoarchaeological research at the Spanish Research Council (CSIC) and at the University of Hamburg. Since 2019 he has been employed at the ALIPH Foundation for the protection of heritage in conflict areas, based in Geneva, where his main focuses are the linkages between climate change, conflict and cultural heritage protection, and the role of documentation and ICT in cultural heritage protection. Co-founder and CEO of Platform Anthropocene Ltd., Andrea leads the development of a comprehensive interdisciplinary web repository on the Anthropocene. He also maintains university teaching in archaeology, heritage and human-environment interaction and acts regularly as a scientific evaluator, rapporteur, and monitor for the European Commission.

MARTIN BELL

Department of Archaeology, University of Reading, Whiteknights, PO Box 217, Reading, Berkshire, RG6 6AH, UK

Email: m.g.bell@reading.ac.uk

Martin is an emeritus professor of Archaeology at Reading University. His research interests are in geoarchaeology, environmental archaeology, coastal and maritime and experimental archaeology. He has been involved in several experimental archaeology projects, particularly the Experimental Earthwork Project. He has been excavating coastal sites in the Severn Estuary for forty years and has produced four monographs on the prehistory of the Severn Estuary. He believes that environmental archaeology has a key role in finding sustainable strategies for nature conservation. His most recent book *Making One's Way in the World: The Footprints and Trackways of Prehistoric People* (Oxbow 2020) explores the ways in which we can investigate prehistoric routeways and connectivity. He is a Fellow of the British Academy and the Society of Antiquaries of London.

NICOLE BOIVIN

Max Planck Institute for the Science of Human History, Kahlaische Strasse 10, 07745 Jena, Germany
Email: boivin@shh.mpg.de

Nicole was a director at the Max Planck Institute for the Science of Human History in Jena, Germany. The author of *Material Cultures, Material Minds: The*

Role of Things in Human Thought, Society and Evolution (Cambridge University Press 2008), she has also been editor of several books, including *Globalisation and the 'People without History': Understanding Contact and Exchange in Prehistory* (Cambridge University Press 2018). She has been awarded research funding from many international bodies, including the European Research Council and the National Geographic Society, is a Fellow of the Society of Antiquaries of London, and holds an Honorary Professorship at the University of Queensland.

CHRISTOPHER EVANS

Department of Archaeology, University of Cambridge, Downing Street, Cambridge CB2 3DZ, UK

Email: cje30@cam.ac.uk

Christopher was the executive director/director of research of the Cambridge Archaeological Unit (CAU), University of Cambridge until 2021. Having worked in British archaeology for over forty years – with his initiation to Fenland archaeology coming at Fengate – following on from the Haddenham Project, he co-founded the CAU with Ian Hodder in 1990. He has directed a wide variety of major fieldwork projects, both abroad – Nepal, China and Cape Verde (the latter sometimes involving Charly) – and in the United Kingdom. A fellow of the Society of Antiquaries of London, in 2018 he was elected a fellow of the British Academy. He has published widely, including monographs arising from both his own landscape projects and those of earlier-era practitioners in the CAU's 'Historiography and Fieldwork' series (e.g. Mucking in 2016). Together with Tim Murray, he edited Oxford University's *Histories of Archaeology: A Reader in the History of Archaeology* (2008).

DAVID FRIESEM

Department of Maritime Civilizations, School of Archaeology and Maritime Cultures, University of Haifa, 199 Aba Khoushy Ave, Mount Carmel, Haifa 3498838, Israel

Email: dfriesem@univ.haifa.ac.il

David is a senior lecturer of environmental archaeology at the Department of Maritime Civilizations, University of Haifa, and a research member of the Haifa Center for Mediterranean History. He combines field archaeology, geoarchaeology, ethnography, and social theory in order to study human ecology, technology, and social interactions, and reconstruct the often-missing small-scale perspective of human-environment interactions. His research interests include human adaptation during the Late Pleistocene, the emergence of complex societies, and hunter-gatherer anthropology.

KASIA GDANIEC

Higher Shippon, Bridge Reeve, Chulmleigh, Devon EX18 7BB, UK

Email: kasia.gdaniec@btinternet.com

Kasia works as an archaeological curator at Cambridgeshire County Council, advising local planning authorities on managing change to the historic environment, and scoping investigation programmes for developers and commercial archaeologists that promote both academic rigour and public engagement. Her particular interests lie in the technical difficulties of preservation *in situ* as a long-term archaeological management technique, the ceramic traditions of Neolithic and Bronze Age Britain, the evolution of the East Anglian fens and the adaptation of local communities to their changing environments, and the history and legacy of post-medieval fen draining schemes and how this shapes current competing land use and environmental pressures.

MICHAEL GILL

48 Saunders Avenue, Salisbury, SP1 3PQ, UK

Email: mjpgbr@gmail.com

Michael has an MA in Landscape Studies (archaeology and history) and an MSc in Geographical Information Systems, both from Leicester University. He works as a GIS consultant with Ordnance Survey, and is an active member of Avon Valley Archaeological Society, where he leads the geophysics survey team. He has a personal research interest in the Neolithic monuments on Cranborne Chase and in the Avon Valley, and has surveyed a number of long barrows and related sites in this region.

LARS ERIK GJERPE

Cultural History Museum, University of Oslo, Frederiks gate 2, 0164 Oslo, Norway

Email: l.e.gjerpe@khm.uio.no

Lars has a Masters and PhD in archaeology from the University of Oslo, with a thesis on Iron Age settlement and property rights in southeastern Norway. He has directed several large-scale heritage management excavations for the Museum of Cultural History at the University of Oslo, mainly targeting Iron Age burials, settlements and agricultural remains, while including other periods and relics. As a result, he has been editor and main author of publications on cemeteries (*Graufeltet på Gulli*, University of Oslo 2005) and Iron Age settlements. Interdisciplinary cooperation and environmental archaeology, including archaeometric analysis (e.g. seeds, charcoal and soil), have been an integrated part of these projects. He has also been editor for the journal *Primitive tider* and academic editor of Trond Løken's 2020 *Bronze Age and Early Iron*

Age House and Settlement Development at Forsandmoen, South-western Norway. Currently, he is a member of the steering committee for large-scale heritage management excavations at the NTNU (Norwegian University of Science and Technology).

MARTIN GREEN

Down Farm, Woodcutts, Salisbury SP5 5R, UK

Email: mgreendownfarm@gmail.com

Martin began a fieldwalking survey as a lad on Cranborne Chase in the latter 1960s. Following experience gained on a number of field projects, he began excavating independently in the region in 1976. He joined Richard Bradley's and John Barrett's Cranborne Chase Project the following year, contributing four site excavations to *Landscape, Monuments and Society* in 1991. He continued independent fieldwork in the early 1990s in collaboration with Mike Allen, in particular on the Fir Tree Field shaft which revealed a remarkable sequence of deposits dating from the late Mesolithic to the Beaker period, and worked with Charly French on the Upper Allen Valley Project 1998–2003, contributing four further site excavations to *Prehistoric Landscape Development and Human Impact in the Upper Allen Valley, Cranborne Chase, Dorset* (2007). Since that time, he has continued independent research, also in collaboration with Josh Pollard and Southampton University, on the Dorset Cursus, on Down Farm and in the Knowlton environs whilst continuing to increase the biodiversity on his small farm. He was made an FSA (Fellow of the Society of Antiquaries) in 2004 and received an honorary Doctor of Science degree from Reading University in 2006.

ANN-MARIA HART

Ann-Maria is currently working in contracts and commercial management within the Australian defence industry, but still maintains an interest in her former career as a geoarchaeologist.

ROBYN INGLIS

York Environmental Sustainability Institute (YESI), K/220, Department of Biology, Wentworth Way, University of York, Heslington, York YO10 5DD, UK
Email: robyn.inglis@york.ac.uk

Robyn is a geoarchaeologist interested in the formation of the archaeological record and its impact on our understanding of Palaeolithic dispersals. After receiving her BA in Archaeology and Anthropology from Cambridge, she gained her MSc in Geoarchaeology from Reading. Her PhD in the McBurney Laboratory focussed on the micromorphological reconstruction of sedimentation at the Haua Fteah, Libya, and its implications for understanding human/environment interactions. From 2011–8 she led geoarchaeological survey in Saudi Arabia

to further understand the Palaeolithic occupation of the Red Sea littoral and its role in hominin dispersals, first as part of the DISPERSE project at the University of York, and later as a Marie Skłodowska-Curie Global Fellow (University of York and Macquarie University). She now works in research development at the York Environmental Sustainability Institute, University of York, and is an Honorary Research Associate in the university's Department of Archaeology.

MARTIN JONES

Department of Archaeology, University of Cambridge, Downing Street, Cambridge CB2 3DZ, UK

Email: mkj12@cam.ac.uk

Martin was the first George Pitt-Rivers Professor of Archaeological Science at the University of Cambridge. He works on archaeobotany and archaeogenetics, in the context of the broader archaeology of food. In his earlier career he explored the development of agriculture in later prehistoric and Roman Europe, after which he was very much involved in the development of biomolecular approaches within archaeology. These he applied to research into the spread of farming of both major and minor crops across Asia, most recently in the context of the Food Globalization in Prehistory Project. His latest project is exploring the co-evolution and Eurasian biogeography of crops and bees.

GABRIELLA KOVÁCS

Matrica Museum and Archaeological Park, 2440

Százhalombatta, Gesztenyés út 1–3, Hungary

Email: antropologus@yahoo.com

Gabriella (PhD) is a museologist and soil micromorphologist at the Hungarian National Museum National Institute of Archaeology. Her main interest is the Middle Bronze Age tell settlement of Százhalombatta-Földvár, under the framework of the international SAX (Százhalombatta Archaeological Expedition) project. Besides this site, other Bronze Age settlements of Hungary are also part of her research interests, regarding the comparison of single and multi-layered settlements of the period, mainly the so-called Vátya Culture. She focuses on the use of space and building techniques via soil micromorphology to add details to traditional archaeological methods.

HELEN LEWIS

School of Archaeology, University College Dublin, Dublin 4, Ireland

Email: helen.lewis@ucd.ie

Helen is an associate professor at University College Dublin School of Archaeology. Her background is in archaeology and anthropology (BA University of

Toronto), environmental archaeology (MSc University of Sheffield) and archaeological soil micromorphology (PhD University of Cambridge). She mostly works today on cave sites in Southeast Asia, but she still loves northwest European Neolithic and Bronze Age monuments and landscapes, and ancient agricultural soils.

JOHAN LINDERHOLM

Environmental Archaeology Laboratory (MAL),
University of Umeå, S-90187 Umeå, Sweden

Email: johan.linderholm@umu.se

Johan trained in archaeology and chemistry, specializing in soils and archaeology (BSc and MSc Umeå University). His PhD dealt with soil chemical aspects on settlement organization over time and general human impact on soils. He has been working with research and contract archaeology in several large projects over the last thirty years, mainly in Scandinavia but also in Gibraltar, Italy, France and the UK. Currently he holds a position as associate professor at Umeå University and is conducting research related to reflectance spectroscopy at the Environmental Archaeology Laboratory (MAL), University of Umeå.

ROY LOVEDAY

School of Archaeology and Ancient History,
University of Leicester, University Road, Leicester
LE1 7RH, UK

Email: r.e.loveday@btinternet.com

Roy is an honorary research fellow in the School of Archaeology and Ancient History, University of Leicester. He completed a PhD surveying cursuses and related monuments of Great Britain in 1985. His particular interests are the societal mechanisms underlying monument plan transmission and construction.

RICHARD I. MACPHAIL

Institute of Archaeology, University College
London, 31–34 Gordon Sq., London WC1H 0PY, UK
Email: r.macphail@ucl.ac.uk

Richard trained in geology and geography, specializing in soil science (BSc Swansea University). An MSc in pedology and soil survey (Reading University) prepared him for a soil science PhD on podzol development on heathlands (Kingston Polytechnic). An English Heritage-funded archaeological soil contract at the Institute of Archaeology (University College London) provided further training and international research opportunities were developed, including working with the Soil Survey of England and Wales and Macaulay Institute, UK, the CNRS, France, and the Soprintendenza, Italy. This led to the publication of *Soils and Micromorphology in Archaeology* (with Courty and Goldberg; Cambridge University Press

1989), the founding of the International Archaeological Soil Micromorphology Working Group, and training weeks at UCL. As a result, *Practical and Theoretical Geoarchaeology* (Blackwell 2006; Wiley 2022) and *Applied Soils and Micromorphology in Archaeology* (Cambridge University Press 2018), both with Goldberg, were written. Macphail is a recipient of the Geological Society of America's Rip Rapp Award for Archaeological Geology (2009), and is a fellow of the Geological Society of America. He is also the 2021 co-awardee (with P. Goldberg) of the International Union of Soil Sciences Tenth Kubiëna Medal for Soil Micromorphology. The paper included here also reflects more than two decades of research across Scandinavia.

WENDY MATTHEWS

Department of Archaeology, University of Reading,
Whiteknights, PO Box 217, Reading, Berkshire, RG6
6AH, UK

Email: w.matthews@reading.ac.uk

Wendy is a specialist in Near Eastern Archaeology and geoarchaeology, focusing on micromorphology of the built environment and long-term perspectives on sustainability (MA Edinburgh 1984; PhD Cambridge 1992, 'Micromorphology of occupational sequences and use of space in a Sumerian city'). She was a research associate and fellow of the McDonald Institute (1993–2000) and is an associate professor in Archaeology at the University of Reading, following a semester as visiting lecturer at UC Berkeley. She was a member of the *Çatalhöyük* team and steering committee, Turkey (1993–2017). She co-directs the *Central Zagros Archaeological Project* investigating the Neolithic of the Eastern Fertile Crescent, Iraq, Iran (2007–), and has conducted research in Syria and Bahrain. She has co-supervised twenty-two PhD students and teaches modules on past, present and future sustainability; micromorphology; and Mesopotamia. She co-designed a new prehistory gallery at the Slemani Museum with Iraqi and Reading colleagues, with sustainability as a central theme.

CRISTIANO NICOSIA

Dipartimento di Geoscienze, Università di Padova,
Via Gradenigo 6, 35131 Padova, Italy

Email: cristiano.nicosia@unipd.it

Cristiano is a geoarchaeologist working as full professor at the Department of Geosciences of the University of Padova, Italy. His research focuses on the study of anthropic deposits, on alluvial geoarchaeology, and on the human impact on soils and landscapes. He is currently the principal investigator of the ERC-funded GEODAP project (GEOarchaeology of DAily Practices: extracting Bronze Age lifeways from the

domestic stratigraphic record). He is involved as chief geoarchaeologist in several Italian archaeological projects and directs the excavations of the Bronze Age site of La Muraiola di Povegliano (Verona) and of the mid-Neolithic site of Molino Casarotto (Vicenza). He collaborates as field geoarchaeologist and micromorphologist in research projects at Olduvai Gorge (Tanzania), Petra (Jordan), Pompeii (Italy), Damyanitsa (Bulgaria), and the Jiroft plain (Iran). In 2017 he co-edited with G. Stoops the volume *Archaeological Soil and Sediment Micromorphology*, published by Wiley.

BONGUMENZI NXUMALO

Department of Anthropology and Archaeology,
Faculty of Humanities, Hatfield Campus, University
of Pretoria, Private Bag X20, Hatfield 0028, South
Africa

Email: u12378624@tuks.co.za

Bongumenzi (PhD 2020, Cantab.) is lecturer in archaeology at the Department of Anthropology and Archaeology, University of Pretoria. His research interests include hydrological modelling, geoarchaeology, the evolution of early state-societies, historical and modern climatic records.

INNOCENT PIKIRAYI

Department of Anthropology and Archaeology,
Faculty of Humanities, Hatfield Campus, University
of Pretoria, Private Bag X20, Hatfield 0028, South
Africa

Email: innocent.pikirayi@up.ac.za

Innocent (PhD 1993, Uppsala) is professor in archaeology at the University of Pretoria. His research interests include geoarchaeology, development of ancient complex societies, water and social formation, and climate change.

FRANCIS PRYOR

Inley Drove Farm, Sutton St James, Spalding PE12
0LX, UK

Email: pryorfrancis@gmail.com

Francis has studied the archaeology of the Fens since 1971. His major excavations in the region took place near Peterborough at Fengate, Maxey and Etton. In 1982 his team's survey of fenland drainage dykes revealed the timbers of a waterlogged Bronze Age timber platform and causeway at Flag Fen, which was opened to the public in 1989. He was a member of Channel 4's long-running series *Time Team*. He has written many popular books including *Seahenge* (2001), *Britain BC* (2003), *Britain AD* (2004), *The Making of the British Landscape* (2010), *Home* (2014), *Stonehenge* (2016) and *The Fens* (2019). His most recent book is *Scenes from Prehistoric Life* (Head of Zeus 2021).

TONKO RAJKOVACA

Charles McBurney Laboratory for Geoarchaeology,
Department of Archaeology, University of
Cambridge, Downing Street, Cambridge CB2 3DZ,
UK

Email: tr251@cam.ac.uk

Tonko is chief research laboratory technician in geoarchaeology at the University of Cambridge. Involved in archaeology since his childhood, he held posts of archaeological site director and museum curator in Serbia (pre-1994) before moving to the UK to specialize in the late Upper Palaeolithic archaeology of ex-Yugoslavia via an MPhil (2004) at the University of Cambridge, and a PhD at the University of Ljubljana (2017). After four years at the Cambridge Archaeological Unit, he took up the post of geoarchaeology technician at the Department of Archaeology in 2008, and since then he has been working at the McBurney Laboratory of Geoarchaeology. He has directed and managed several archaeological projects, field and laboratory training in the UK and eastern Europe. He has authored several volumes and articles, including a monograph on preventive archaeology in ex-Yugoslavia published by Belgrade's Institute of Archaeology (2019) and a manual of archaeological excavation (co-authored with J. Appleby, 2015).

ROB SCAIFE

Palaeoecology, University of Southampton,
University of Southampton University Road,
Southampton SO17 1BJ, UK

Email: r.scaife@soton.ac.uk

Rob is a visiting professor of palaeoecology and environmental archaeology at the University of Southampton, and an honorary research associate of the McDonald Institute for Archaeological Research at the University of Cambridge. His first degree was in geography with geology, and an interest in the Pleistocene led him into palynology. He investigated the Late and Post-glacial vegetation changes of the Isle of Wight for his PhD (King's College London). Subsequently, he worked at the Institute of Archaeology, London, and the Ancient Monuments Laboratory at English Heritage. As a freelance palaeoecologist, he has continued to work across southern and eastern England, along with international studies in Italy, Turkey, Peru and Chile.

SIMON STODDART

Magdalene College, Cambridge, CB3 0EU, UK

Email: ss16@cam.ac.uk

CAROLINE MALONE

8 Lansdowne Road, Cambridge, CB3 0EU, UK

Email: c.malone@qub.ac.uk

Simon and Caroline have been engaged in the research of ancient landscapes for nearly forty years, with a

focus on the central Mediterranean. They both attended lectures by Keith St. Joseph, Richard West, Nick Shackleton and John Coles on the outlines of environmental archaeology. Simon Stoddart went on to study with Bill Farrand and Donald Eschmann at the University of Michigan. Caroline Malone worked at Fengate under the inspired guidance of Francis Pryor, where Charly French also undertook his early geoarchaeological work. They both collaborated in their first major project in the 1980s with Edoardo Biondi, Graeme Barker, Mauro Coltorti, Rupert Housley, Chris Hunt, Jan Sevink (and his pupils Peter Finke and Rene Fewuster) in the regional study of Gubbio. It was, though, the later study of the uplands of Troina at the turn of the millennium in Sicily with Charly French and Gianna Ayala that opened their eyes to new ways of understanding geoarchaeology. This led to the in-depth collaboration with Charly on the island of Malta, entitled FRAGSUS (PI Caroline Malone), which substantially interrogated the rationale for the stability and fragility of the ecology of the Maltese temples. The collaboration lives on through the prospect of continuing work with Charly's pupils, notably Federica Sulas, Gianbattista Marras, Petros Chatzimpaloglou, and Sean Taylor. Caroline Malone is a professor emerita of prehistory at Queen's University Belfast and Simon Stoddart is professor of prehistory at the University of Cambridge.

FRASER STURT

Southampton Marine and Maritime Institute,
University of Southampton, Avenue Campus,
Southampton SO17 1BF, UK
Email: F.Sturt@soton.ac.uk

Fraser is a prehistorian and marine geoarchaeologist who focuses on the Mesolithic/Neolithic transition in submerged, coastal and island contexts.

FEDERICA SULAS

Charles McBurney Laboratory for Geoarchaeology,
Department of Archaeology, Downing Street,
Cambridge CB2 3DZ, UK
Email: fs286@cam.ac.uk

Federica (PhD 2010, Cantab.) is a senior research associate at the McDonald Institute for Archaeological Research, University of Cambridge. Her research interests include geoarchaeology and landscape historical ecology.

MAGDOLNA VICZE

Matrica Museum and Archaeological Park, 2440
Százhalombatta, Gesztenyés út 1–3, Hungary
Email: vicze@matricamuzeum.hu

Magdolna (PhD) is an archaeologist with primary interests in household archaeology. She is working in the National Institute of Archaeology of the Hungarian National Museum as a Bronze Age researcher and is the leader of the SAX Project (Százhalombatta Archaeological Expedition). The archaeological expedition at Százhalombatta is a long-term international research program with the aim of studying the life and daily activities of prehistoric people at a Bronze Age tell settlement. Her other interest is in mortuary practices.

Chapter 6

Soil pollen analysis: a waning science?

Rob Scaife

The period of greatest use of soil pollen analysis as a means of determining local vegetation and environments, especially in relation to archaeological sites, came with the establishment of archaeological science as a discipline during the 1960–70s. Recent decades, however, have seen the demise of this technique such that where soil pollen analysis is undertaken, many of the factors needed for interpretation are not realized. Of very substantial importance to the understanding of soil pollen profiles has been the continuing development of soil micromorphological studies. Where the two disciplines are undertaken in conjunction, the data obtained greatly complement each other, providing a better understanding of the soil and the past vegetation and environment of archaeological sites. This contribution examines briefly the history and techniques of soil pollen analysis and its value to archaeology.

Introduction: a background to soil pollen analysis

Pollen analysis has traditionally been carried out on peat and lacustrine sediments providing vegetation and environmental histories, often with substantial time spans and a wide geographical range. Soil pollen analysis contrasts in providing localized vegetation records from non-wetland sites. From the 1950s, this relatively new discipline was expounded in the UK by Dimbleby (1950; 1952a; 1955; 1957a,b; 1961a,b; 1962), and by Waterbolk (1953; 1957; 1958) and Groenman-van Waateringe (1978) in the Netherlands, both having a particular interest in archaeological buried soils and old land surfaces, especially sub-barrow profiles (Andersen 1995). In France, pioneer work on pollen in acidic soils was carried out by Guillet (1970; 1971a,b). The value of examining deep woodland mor humus was recognized in Draved Forest, Denmark, by Iversen (1964) and Andersen (1979), producing long woodland histories, back to 6300 BP (c. 4280 BC); Stockmarr (1975) similarly examined deep mor humus profiles

at Mantingerbos, the Netherlands, also stressing the value of their stratification and for establishing past local woodland and environments.

Although Dimbleby's soil pollen analysis is largely known from his analyses of archaeologically related features, especially palaeosols, he pioneered the research and development of soil pollen analysis as part of his work for the Forestry Commission at Oxford. It was because of his need to understand the past vegetation and soils of largely heathland zones that he turned to the evidence which could be obtained from buried soils, especially those underlying prehistoric monuments (Dimbleby 1952b; 1953; 1957b). Dimbleby's (1950) doctoral dissertation, 'The ecology of some British podzol formations', examined soil formation in relation to vegetation history. This work pioneered the study of pollen preserved in soils under Bronze Age barrows and field boundary banks of North East Yorkshire and the New Forest, England. His examinations of pollen profiles in acid, podzolic soils demonstrated the establishment of heathland after woodland clearance which caused soil degeneration, and that podzolic soils are ideal for pollen preservation. This early research work was encapsulated in *The Development of British Heathlands and Their Soils* (Dimbleby 1962), establishing the long-term history of these environments (Dimbleby 1976b). As a corollary to this work he also examined the mechanics of pollen in soils (Dimbleby 1961a,b) and the possibility of soil regeneration of podzolic soils (Dimbleby 1962). This aspect of palynology at the time contrasted markedly with the traditional approach of studying past vegetation through the analysis of stratified peat and lacustrine sediment and, as such, was not without criticism from the 'established' school and especially by Godwin (1958). However, data obtained from such prehistoric contexts established Dimbleby within the newly developing field of environmental archaeology,

embodied in Brothwell and Higgs' (1963 (1969)) textbook *Science in Archaeology* (Dimbleby 1969; Ucko & Dimbleby 1969). His specific techniques were adopted by a number of analysts throughout the U.K. (e.g. Bayley 1975; Baigent 1976; Balaam 1984), largely by students from the Institute of Archaeology, University College London. Dimbleby's methodology and characteristic pollen diagrams are not frequently mentioned in current research literature, but they deserve to be highlighted and are described below.

Although not carried out with such intensity as Dimbleby's research, which produced some hundreds of analyses, important pioneering work was carried out in Europe by Waterbolk (1950; 1954; 1956; 1957), who adopted different and more standard techniques to examine palaeosols and determine past environment and environmental change. His work on palaeosols and old land surfaces underlying Neolithic monuments on heathland in the Netherlands (Waterbolk 1956) demonstrated that heathland formed in the wake of human impact on woodland and subsequent soil deterioration. Early archaeological analyses of ditch fills and funerary barrows on similar pedologies were carried out in the Netherlands by Groenman-van Waateringe (1978; 2012), Groenman-van Waateringe and Spek (2015/2016) and Casparie and Groenman-van Waateringe (1980), including studies of multiple sub-barrow soils and old land surfaces, as well as in Denmark (Andersen 1995). Such works not only established characteristics of the overall environments but were able to document change from woodland to heath associated with pedological changes. Other investigations of soil character and development were undertaken using pollen by Iversen (1969) in his seminal work on pedological change through interglacial cycles, and by Stockmarr (1975) on the character of (copro- and myco-) mor humus. Subsequent studies tended to address particular sites, and issues such as past land use (Vuorela 1970; 1976; 1982; Sergerstrom 1991).

More recently, a number of critical appraisals of soil pollen and its interpretation have been forthcoming. These are examined below through a review of studies that question the taphonomy of soil pollen, shedding light particularly on how pollen becomes incorporated throughout a profile and how this may vary in differing soil types and geographical zones.

Taphonomy of pollen in soil

Dimbleby's premise was that pollen, liberated by flowers and by spores from non-flowering plants, contributes to the atmospheric pollen rain. After settling on the land surface, most is destroyed through

oxidation and/or microbial and microfaunal activity. In fortuitous circumstances, however, pollen may be preserved in certain types of soil where such processes are inhibited, especially in acidic podzols, and can be extracted to provide data on past vegetation and environments. Importantly, this contrasts with lacustrine sediments and peat accumulation under anaerobic conditions, where the upward accumulation of sediments provides a vertical stratigraphic record of changing vegetation and habitats at a local and more regional scale.

There is a general downward movement in soils and sediments of pollen aided primarily by water flow, largely rain. Pollen and spores, however, do not move downwards as individual grains but are locked in humic colloids, and the downward movement is, therefore, slow, and the breakdown and release of grains from the colloids depends on various pedological conditions. The humus complexes tend to keep pollen in broad layers in which they were originally deposited. This results in a crude stratification of pollen within the soil profile with the oldest, irrespective of grain size, at the base of the profile. A soil pollen profile is, however, not truly stratified, as while the youngest pollen is largely at the top and oldest lower down, at any particular level there may be pollen of various ages (Dimbleby 1985). Longer residence in soils, and the effects of bacterial action and physical and chemical decay reduce the number of pollen grains present, resulting in differential preservation in favour of the most robust types. In Britain, these are often *Lactucoideae* (dandelion types) and fern spores. In acidic soils with no faunal mixing, the highest absolute pollen numbers are in the upper levels, especially the humic Ah horizon, and decrease with depth. Thus, calculation of absolute pollen frequencies is an important tool in interpreting soil pollen data/assemblages, coupled with knowledge of the differential preservation/resilience of various pollen types in varying soil and sediment types (Havinga 1964; 1967; 1971). Long-term study of taphonomic processes has been carried out to aid interpretation of palaeo-pollen spectra (e.g. Sangster & Dale 1961; Jewell & Dimbleby 1966; Dimbleby 1974b; Havinga 1974; 1984).

Other aspects affecting pollen preservation include microbial attack, oxidation, corrosion, temperature and the physical composition and thickness of the pollen wall. The preservation of pollen in soils and, in most cases, the differential preservation noted, is clearly fundamental to the interpretation of soil pollen data. Havinga's (1964; 1967; 1971; 1974; 1984) seminal studies remain the most authoritative research on the susceptibility to different forms of deterioration in varying types of soil profile and the resulting consequences

in interpreting pollen data. Havinga (1963) initially examined the arguments of downwash of pollen as promoted by Dimbleby (1985, 50–5), as opposed to mixing through biological activity, and stressed that preservation may be a function of a number of taphonomic factors: namely microbial attack, oxidation, corrosion, mechanical forces, sporopollenin (pollen wall) robustness and composition, and temperature. Typically, pollen of taxa such as the Lactucoideae (fenestrate pollen of dandelion types) are robust and may have long residence time in soil compared to thin-walled taxa, thus leading to significant overrepresentation and skewing of pollen assemblage data.

Interpretation of such stratified soil pollen requires a different approach to that of peat and lacustrine sediments. However, the only principal contradiction to this is if they come from soils where there is a build-up of a surface humus horizon, as in a podzolic heathland soil (Ah) or woodland mor humus. There may be a stratigraphical accretion of pollen upwards as humus continues to accumulate and may produce long vegetational histories as documented in Draved Forest, Jutland, Denmark (Iversen 1964; Andersen 1979). Here, a remarkably thick and pollen-rich mor humus developed on earlier mull under climax woodland. There occurred a retrogressive change from *Tilia* forest with *Quercus* and *Corylus* to *Quercus*, *Betula* and *Fraxinus* and finally *Quercus*, *Fagus* and *Ilex*. High biological activity and breakdown of plant cellulose is carried out by microorganisms and fungal activity. With the former, ingested pollen is excreted to form *copromor*, and with the latter *mycomor* (Stockmarr 1975). Changes in woodland structure through human activity may result in a change from mull to mor humus, rate of accumulation and, with increasing acidity, better pollen preservation (Iversen 1964; Aaby 1983). In such mor humus, pollen may be remarkably abundant with many millions of pollen grains per cubic centimetre. For example, a Bronze Age woodland humic podzol underlying a bank at Hengistbury Head, Dorset, England, produced in excess of twenty million grains per cc (Scaife 1992).

Advancing podzolization implies the soil is becoming degraded, and with this is a reduction of faunal, especially earthworm, bioturbation, better pollen preservation and a degree of stratification. As noted, this process is best observed with change from forest brown earth soil, which has been degraded through clearance and cultivation, with soil depletion providing a suitable habitat for heathland vegetation. There are, however, clear differences between this typical situation and other soil types. In complete contrast to such pollen-rich mor humus noted, calcareous rendzina type soils, such as found on the chalklands

of southern England, have proven problematic for pollen preservation, with all of the factors suited to ideal preservation being absent (high pH, oxidation, faunal mixing). Analyses of often well-defined palaeosols underlying field monuments have been summarily discounted for palynological analysis in spite of the fact that the past/prehistoric ecology of the chalk and other limestone lithologies has remained enigmatic. However, pollen may indeed be obtained from such contexts using larger sample volume and more specialized extraction techniques. Occasional analyses showed that useful information can be obtained, such as a late-glacial (Windermere) interstadial dated profile at Brook on the Kentish Downs (Lambert 1964), later recalibrated by Preece (1994).

It was Dimbleby and Evans (1974) who demonstrated the real value of examining soil pollen combined with molluscan analysis in calcareous palaeosols underlying Neolithic barrows, enclosures and henge structures on the chalk of southern England, for instance at Beckhampton Hill, South Street, Avebury, Windmill Hill, Durrington Walls, and Knap Hill. This has proven valuable for the Downs of Kent and Sussex and Wiltshire (Salisbury Plain) that have had a paucity of palaeo-vegetation data and an enigmatic palaeo-vegetation record due to the absence of suitable peat and lacustrine sediments for 'normal' analysis in other environments (Turner 1970; Allen & Scaife 2007). Soil pollen studies of calcareous rendzina soils at important pollen sites, such as Silbury Hill (Dimbleby 1997; Robinson 2002; 2003), came to complement palaeoenvironmental records from the study of mollusca in colluvial profiles, showing that attempts to study pollen even in these environments are worthwhile. The processes affecting pollen distribution in such biologically active, calcareous soils were examined by Dimbleby and Evans (1974; Dimbleby 1974b) and through the long-term experimental earthwork studies at Overton Down, Wiltshire (Dimbleby 1966) and subsequent staged analyses (Crabtree 1996; Crowther *et al.* 1996; Kelley & Wiltshire 1996).

Whilst the majority of soil pollen studies relate to archaeologically buried soils, or indirectly to them as through colluviation, for example (Riezebos & Slotboom 1974), it should be noted that analyses of non-buried mineral soils have also been undertaken. Such studies are again largely attributed to Dimbleby, who showed heathland development through soil deterioration in his early work on forestry in the North York Moors, and documented woodland regeneration in podzols at the New Forest, Hampshire (Dimbleby & Gill 1955; Dimbleby 1962).

There are now numerous pollen studies which show that *Tilia cordata* was the dominant woodland tree

across much of southern and eastern England during the middle and later Holocene. Tauber (1967) observed the abundance of pollen trapped in the bark of trees and there is the possibility of this pollen being flushed from the tree bark and into adjacent soil. Keatinge (1982; 1983), in an important but not widely known study, examined the mode of transfer and problems of representivity of this robust (*Tilia*) pollen type in soils and sediment at Iping Common, West Sussex. This suggested that discrete pollen assemblage zones arise from the incorporation of pollen into the soil by successively shallower burrowing earthworm populations. As the soils changed from mull to mor type, there is typical pollen evidence of change from mixed deciduous woodland of *Quercus*, *Tilia* and *Corylus* with fern rich understorey, to scrub woodland with *Betula* and *Corylus* and *Pteridium* understorey, to *Calluna* heath on podzolic soils, as exists today.

Given these factors, it is clear that each soil profile must be considered in terms of a range of factors and not as one would consider the pollen assemblages from lacustrine and peat sequences. Here soil micromorphology plays a fundamental role in understanding the taphonomy of the pollen, placing the pollen and, thus, the reconstructed vegetation and environment in relation to previous land use, on-site archaeology and also, for an understanding of the environment, to pedogenesis. In addition, micromorphological analysis has aided understanding and debate as to the processes of pollen translocation in soil.

Discussion of Dimbleby's interpretation of pollen incorporation into soil has been evaluated by a number of researchers, some incorporating observations from soil micromorphological studies, but there has been little recent research on this. Whilst Dimbleby considered that downwash of clumped pollen in humic colloids was the principal mechanism of incorporation, others have considered movement as individual pollen grains through void spaces (Kelso 1974), or the movement and distribution of pollen as the result of bioturbation. Walch *et al.* (1970) and Andersen (1979) consider pollen distribution to be due to bioturbation by invertebrates rather than downwash of humic material. Similarly, Davidson *et al.* (1999; Tipping *et al.* 1995; 1997), using fluorescence microscopy of pollen in conjunction with soil micromorphology, showed that soil organisms are responsible for the distribution of pollen in soil. In acidic podzols, however, this may not always be the case as only the surface organic mor humus (Ah) may have a stratigraphical build-up of humic material through lack of earthworm activity. Where human activity has resulted in past soil degradation, pollen evidence of past land use in lower soil horizons of neutral or higher pH will be bioturbated, especially

through earthworm activity, and homogeneously distributed throughout. If subsequent acidification and humic downwash later occurred, a broad pollen stratigraphy may be found as described by Dimbleby. In the upper Ah, a more detailed stratigraphy may also be present even though microfaunal activity may have caused some mixing.

In reality, it is probable that a range of these factors should be taken into account, depending on the nature of the soil in question. Van Mourik (1999) emphasizes that soil micromorphological studies are important to the investigation of pollen in soils and soil processes resulting in infiltration and the differential preservation of pollen. His studies of colluvial deposits with intercalated Pleistocene cambisols in Galicia, Spain, demonstrated phases of ecological development during the deposition of soliflucted layers (van Mourik 1999). Tipping *et al.* (1995; 1997) further elaborate on the need to understand the stratigraphical integrity of pollen data in relation to soil formation and character. Tipping *et al.*'s (1994) investigations of palaeosols on Biggar Common, Scotland, produced positive results in relation to archaeology, and in Sweden, Florin (1975) similarly attested to stratification of pollen in the upper A-horizon soil, essentially mirroring Dimbleby's view that the upper part of buried soils and old land surfaces has more integrity, whilst differential preservation of robust types typically occurred in the lower soil profile. In spite of these factors, it is clear that soils buried beneath earthen structures such as funerary monuments or field boundary banks may provide pollen data which are representative of the vegetation and environment immediately prior to soil burial, if that soil has not been truncated in the process of site construction.

As noted above, Dimbleby pioneered the pollen analysis of palaeosols underlying Bronze Age prehistoric mounds and other earthen structures such as field boundary banks and ramparts (e.g. Dimbleby 1971), and there have been many subsequent studies (e.g. Tubbs & Dimbleby 1965; Eide 1981; Catt *et al.* 1987). There have been numerous studies in Britain and Europe which have demonstrated (as noted above), the change from woodland (climax vegetation) to heathland, with change from mull to podzolic soils with mor humus caused by human activity and consequent soil degradation. This is shown in Dimbleby's classic work at Iping Common, which showed the establishment of heathland due to prehistoric woodland clearance and subsequent soil degradation (Dimbleby in Keefe *et al.* 1965). Other examples include Minsted, Sussex (Dimbleby 1974a) and West End Hampshire (Dimbleby 1976a), classic Dimbleby analyses of Bronze Age barrows constructed using inverted turves cut from

the surrounding landscape to form the central core. The former shows an acid podzol with good pollen preservation, typically showing pre-barrow woodland comprising *Quercus*, *Corylus* and *Alnus*. Increasing *Calluna* at this time also suggests that some soil deterioration had occurred prior to construction of the barrow, probably the result of woodland clearance. The latter site is also a good example of the presence of *Hedera helix* (ivy) pollen in a lower soil. This phenomenon, described as seemingly inexplicable, was later discussed by Simmons and Dimbleby (1974) and suggested as coming from the collection of ivy for feeding deer during winter months. There are many other pollen analyses from English lowland heath illustrating the creation of heathland from dominant woodland, often with an intervening phase of scrub (hazel) colonization (Rankine *et al.* 1960; Simmons & Dimbleby 1974; Baigent 1976; Dimbleby 1976a,b; 1985; Palmer & Dimbleby 1979; Scaife & Macphail 1983; Scaife 1985).

The pollen method

Preparation techniques are generally standard (Faegri & Iversen 1964 and later editions; Guillet & Planchais 1969; Moore & Webb 1978; Moore *et al.* 1991), although samples larger than the typical 1 ml/1 cc of peat or lake sediment are frequently used in soil palynology. Certainly, in the case of calcareous/rendzina soils, samples as large as 10 ml or more may be necessary to recover sufficient pollen for reasonable counts to be made. Extraction is now aided by use of micromesh sieving and elutriation and/or decanting in large volumes of water to remove much of the clay/fine silt extraneous mineral material prior to hydrofluoric acid (HF) treatment. The introduction of known quantities of 'exotic' pollen or spores to a known volume of sediment is used in the analysis of peat and lake sediment, where radiocarbon dating allows the construction of age-depth models and pollen influx data (calibrated aliquots as used by Dimbleby may also be used). The measurement of absolute pollen frequency in soil takes on a different role. As noted, there is in general a reduction of pollen numbers down a soil profile. In many cases an old land surface and palaeosol under a monument may not always be visible due to the effects of later pedogenesis. Recording absolute pollen and fern spore frequencies throughout such a profile may show the position of the old land surface, and in some cases the position of structural turves (and whether they are inverted). Once identified, multiple turves taken from the surrounding area may produce a number of mini pollen profiles revealing past on- and near-site vegetation.

The possibility of changing differential preservation was illustrated by Dimbleby's diagnostic technique of representing pollen data. For each taxon, percentages are given on the right of the vertical (Y) axis and the measured APF on the left (Fig. 6.1). This illustrates the value of APF calculations in interpreting soil pollen assemblages in terms of differential preservation of individual taxa down a profile. The much-published pollen diagrams of Iping Common (Dimbleby in Keefe *et al.* 1965) and Rackham in Sussex (Dimbleby & Bradley 1975) demonstrate his technique, and were also used by Dimbleby to explain the incongruity of pollen in relation to archaeology and artefact distribution in certain soil pollen profiles, due to soil faunal mixing. This technique of pollen data depiction is now rarely, if ever, used with more normal presentation with overall rather than individual APF values plotted, thus relying on knowledge of specific preservation characteristics of pollen taxa.

From recent enquiries to the writer for pollen analysis of archaeologically related soils, there often seems to be a lack of understanding of the relationship of artefacts in a soil profile. There is the expectation that pollen recovered from the same levels as artefacts may provide data on past vegetation concurrent with the human activity represented. This is clearly not the case, especially on 'open sites'. Darwin's (1881) pioneer studies demonstrated earthworm processes, and in more recent times Atkinson (1957) and Canti (2003) (papers well worth reading), discussed the displacement and incorporation of small objects into soil profiles through faunal (largely earthworm) activity. Atkinson suggested this occurred at a rate of two inches in a decade and lasted for thirty years. This is clearly significant to the stratigraphical distribution of archaeological artefacts in contemporary and ancient soil profiles. The concept of archaeological artefacts recovered from soils of a different type to that on which they were originally deposited, was examined by Dimbleby in his often-quoted classic studies of the distribution of Mesolithic artefacts in now acid soils at Iping Common, Sussex (Dimbleby in Keefe *et al.* 1965) and of the distribution of Neolithic artefacts in relation to pollen horization at Rackham, Sussex (Dimbleby & Bradley 1975). At the former (see Fig. 6.1), Dimbleby also demonstrated the establishment of heathland due to prehistoric woodland clearance and subsequent soil degradation. Whilst initially soils were brown earth mull, subsequent deforestation, soil depletion and development of *Calluna* heath would have led to extinction of earthworms and the development of the podzolic soil in which the artefacts are now found. Both sites have artefacts incorporated into the soil through earthworm activity, and these are not associated with the buried soil.

Research archaeological and experimental studies

The trend towards experimental archaeology arose out of the development of archaeological science as a discipline. Pollen taphonomic studies were carried out at Overton Down, Wiltshire (Jewell & Dimbleby 1966; Crowther *et al.* 1996) and Wareham Heath, Dorset (Dimbleby 1974b; Macphail *et al.* 2003), the former on calcareous lithology and the latter on acid substrate. These sought to examine questions such as movement of biological remains in these contrasting soil types, and represent, perhaps, the most ambitious research because of their long-term aims. Initially, Dimbleby (Jewell & Dimbleby 1966; Dimbleby 1974b) was responsible for establishing studies of pollen and spore movement in soils, using *Lycopodium* spores sprinkled over the surface prior to establishment of the earthwork.

Whilst pollen preservation is usually marginal in calcareous soils such as Overton Down, this was not the case at this experimental site and previous analysis of a nearby, sub-Bronze Age barrow soil was able to establish the earlier presence of prehistoric woodland. With increased interest in soil micromorphology, these sites offered a unique opportunity to further relate microfossil movement and taphonomic processes at Overton Down (Crabtree 1996) and Wareham (Macphail *et al.* 2003). Old floors and land surfaces are commonly encountered and examined to determine local activities, and sampling, both spatially for determining areas of activity as well as vertically/stratigraphically for temporal changes, may be undertaken, as in the Late Bronze Age hut floors at Must Farm, Cambridgeshire (Scaife forthcoming). At Butser Ancient Farm, Macphail *et al.* (2004; 2006) demonstrate observable differences between experimental domestic floor and stable deposits using soil, chemical and palynological studies. Here, unusual pollen preservation in otherwise unsuitable, calcareous material is explained as an outcome of organic and phosphate-rich deposits, which also resulted in homogeneous soil and micromorphological characteristics.

The taphonomy of pollen may be complex in such circumstances, with the possibilities of trampling and disturbance, and the inclusion of secondary/derived pollen from domestic refuse, floor covering, food waste, and human and animal faecal material, all of which may contain secondary pollen (Macphail *et al.* 2004; Cruise & Macphail 2000). Combined soil micromorphology with pollen helps to determine such aspects, and the complicated taphonomy (Macphail *et al.* 2004). Sageidet (2005) provides a further, continental example (Norway), of the analysis of prehistoric/Bronze Age podzolic soil and comparison with an adjacent/

nearby clearance cairn. Pollen and pedological/micromorphological data demonstrate correlation between cultivation and the stone clearance cairns. As with many other sites, there is clear evidence of bioturbated brown earth soil which, subject to agriculture, became degraded, and the development of an acid podzol.

Cultivation history is obviously of significance to archaeologists. Traditionally, observation of past field boundaries and subsoil plough marks are some of the best indicators. Palynological studies of agricultural development have been forthcoming by Vuorela (1970; 1976; 1982) in Finland, demonstrating slash-and-burn agriculture with clearance, cultivation, grazing and forest regeneration in the late nineteenth century. In Jutland, Denmark, Sergstrom (1991) studied thin mor humus layers to identify arable clearance phases dating from the Iron Age to more recent times. Ropke *et al.* (2011) similarly studied Bronze Age to Middle Ages land-use systems and environmental change spanning the last 3,500 years. Environmental analyses including pollen analysis of both peat profiles and colluvial sediments demonstrated pastoral phases relating to climate, especially to the Little Ice Age, economic, social and cultural changes. Odgaard & Rostholm (1987) analysed Bronze Age sub-barrow soils (2600 BC) in Jutland, showing a transition from deciduous woodland to heathland podzol instigated by forest clearance and subsequent soil degradation. Similar examples come from Norway (Sageidet 2005) and the Netherlands (van Mourik *et al.* 2012). Dijkstra and van Mourik (1996) combined soil micromorphology and pollen analysis of young acidic mor humus soils in the Netherlands, and studied forest dynamics in terms of plant litter production and decomposition in relation to soil development. Contrasting with many studies of prehistoric sites, which show change from woodland on brown earth soils, soil degradation through human activity and consequent podzolization, this study showed local change from acidic soil under open heath to (pine) forest. As well as Dimbleby's premise of pollen being broadly stratified and of different ages, this study also demonstrated the importance of pollen in micro-faunal (non-earthworm) excrement.

Even palaeoscatological studies may play a part in understanding the pollen make-up of soils, with the possibility that pollen within faecal material disposed of in gardens, as waste or in manuring of horticultural plots, in rivers on floodplains and in many other archaeological features, may contribute to the diversity of pollen assemblages recovered from archaeological contexts. It is well understood that pollen from the cereal inflorescences may remain with the harvested crop during crop processing, and become incorporated into farinaceous food products (Robinson & Hubbard 1977)

and, once eaten by humans or animals, pass through the digestive system. Where such faecal material is present, past agriculture and diet can be ascertained (Greig 1981; Scaife 1986). Such factors need to be taken into account when examining archaeologically based soil and sediment. Where faecal debris is present, soil micromorphology has assisted in determining the possibility of such secondary pollen sources.

Evidence of the value of combined soil micromorphology and palynological studies has been forthcoming from interdisciplinary studies from excavated sites, some from appendices to monographs of developer-funded excavations and not often quoted in mainstream publications. These date back from the 1980s on, with combined micromorphological/pollen analyses of sub-barrow palaeosols, for example, at West Heath, Sussex (Macphail 1985; Scaife 1985) and Deeping St. Nicholas, Lincolnshire, (French 1994; Scaife 1994), both on acid substrates. More extensive landscape histories based on combined pollen studies of nearby peat and soil pollen with soil micromorphological and other pedological studies have been forthcoming (e.g. Whittington & Edwards 1999). The chalklands of Cranborne Chase (French *et al.* 2007), as noted above, are problematic for pollen analysis, but have provided long-term landscape history from soil micromorphology, pollen and mollusca. From the palynologically 'easier' heathland environment of Poole Harbour, Dorset (Branch & Scaife 1991; Scaife 1991) and Exmoor (Carey *et al.* 2020; 2021) similar landscape histories have been obtained.

Such integrated studies also come from further afield. Soil pollen studies attempted in the tropics have been less successful because of the high biological activity and other climatic conditions, ranging from high rainfall and humidity to intense dry conditions. Horn *et al.* (1998), working in Costa Rica, demonstrated that high pollen values were present in well-preserved soil, showing episodes of forest clearance and secondary woodland succession. However, this study showed that in such biologically active systems and climatic regimes, rapid downwash occurred in soil through high rainfall and with strong bioturbation, resulting in a lack of coherent stratigraphy and pollen only representing a few decades of vegetation and a very local environment. In Columbia, however, Herrera *et al.* (1992), in order to establish modern, efficient agriculture, have studied past soil and agricultural changes spanning 800 years in the Aracuan region of the Columbian Amazon. Also in South America, Branch *et al.* (2007) have examined terrace palaeosols dated between c. AD 615–1400 (Middle Horizon and Late Intermediate periods) in the Peruvian Andes. Sedimentological analysis of palaeosols coupled with

pollen obtained from adjacent sediments demonstrated terrace construction for cultivation of maize.

Extensive field survey on Easter Island (Rapa Nui), by Prof. S. D. Hamilton (Armstrong *et al.* 2017) identified palaeosols associated with a number of monuments (*moai*) which are being severely eroded in the Poike region. Sampling for recovery of palaeoenvironmental data pertinent to the well-documented deforestation of the island was carried out. The monument Ahu Hati te Kohe is suffering severe erosion and degradation and before the loss of this monument and its associated palaeoenvironmental contexts, the palaeosols were sampled by the writer in 2017. An integrated soil micromorphology and pollen study was carried out on profiles from under the construction and from closely adjacent palaeosols (Scaife & French 2018). Pollen analysis suggests that palm forest was present at the time of *moai* construction. However, soil micromorphology shows some truncation of the 'A' horizon, and thus a possible time period when clearance prior to construction of the monument may have taken place. Analysis of an adjacent palaeosol indicates the former, but final resolution of this awaits further examination of buried soils from under the monuments; nevertheless, this illustrates the value and often necessity of adopting an integrated pollen and soil micromorphology approach.

Conclusion

This contribution seeks to provide a background to the development and study of soil pollen analysis and its value, especially to archaeology. After what might be regarded as the pinnacle of this discipline during the latter part of the twentieth century (1970–80s), associated with the rising awareness of environmental archaeology as a discipline, environmental analyses were frequently required, where appropriate, as part of developer-funded site investigations. Such analyses have become much scarcer in the past two decades, such that the techniques and understanding of soil palynology have become obscure. There is an evident value of interdisciplinary studies (van Mourik 1999; Macphail & Cruise 2001; French 2003; 2015; van Mourik *et al.* 2012) and especially liaison between soil micromorphology and palynology. Whilst the majority of soil pollen analyses are site-specific and end up as appendices to the archaeology, attempts to understand soil pollen taphonomy have important implications for interpreting site formation processes. The advancement of studies in soil micromorphology has helped in understanding the processes of past soil formation, and thereby, the long-debated processes of pollen incorporation into a soil profile. In many

cases, this may be vital to the interpretation of pollen assemblages obtained in relation to archaeological remains, and for the correct interpretations of the past, archaeologically contemporaneous vegetation and environment. This is especially pertinent in relation to ascertaining such aspects as soil truncation prior to burial and subsequent modifications by later pedogenesis of archaeologically important horizons. Such integration may not be apparent in many publications, but background dialogue between pollen and micromorphological analysts regularly occurs to ascertain such factors, and thus the contemporaneity of pollen with the matrix and the archaeology. There is, however, a paucity of expertise in both disciplines of soil palynology and soil micromorphology, such that there are relatively few published, integrated methodological studies and site data, compared to the increasing wealth of environmental and archaeological science analyses. It is clear that further research is required on the taphonomic processes of pollen in

soil and many research projects remain. Subsequent to his retirement, this view was strongly expressed by professor G.W. Dimbleby (pers. comm.).

Acknowledgements

I should like to thank my friend and mentor in soil palynology, the late and great Geoffrey Dimbleby. Subsequent to his retirement, I spent many hours as a friend of Prof Dimbleby, discussing the subject of pollen taphonomy in soil, during which he expressed the view that much more research was required. I should also like to thank the soil micromorphological analysts who have helped to unravel the status of pollen in my analyses, especially Charles French and Richard Macphail. Thanks to Catherine Langdon and Wendy Scaife for their useful comments on this contribution. Finally, many thanks to the editors of this volume for its inception and their hard work in editing contributions.

Inspired geoarchaeologies

Geoarchaeological research captures dimensions of the past at an unprecedented level of detail and multiple spatial and temporal scales. The record of the past held by soils and sediments is an archive for past environments, climate change, resource use, settlement lifeways, and societal development and resilience over time. When the McDonald Institute was established at Cambridge, geoarchaeology was one of the priority fields for a new research and teaching environment. An opportunity to develop the legacy of Charles McBurney was bestowed upon Charles French, whose 'geoarchaeology in action' approach has had an enormous impact in advancing knowledge, principles and practices across academic, teaching and professional sectors. Many journeys that began at Cambridge have since proliferated into dozens of inspired geoarchaeologies worldwide. This volume presents research and reflection from across the globe by colleagues in tribute to Charly, under whose leadership the Charles McBurney Laboratory became a beacon of geoarchaeology.

Editors:

Federica Sulas is a senior research associate at the McDonald Institute for Archaeological Research, University of Cambridge. Her background is in oriental studies and African archaeology (BA Hons, Naples) and geoarchaeology (MPhil & PhD, University of Cambridge). Her main research interests are in landscape historical ecologies and water-food security.

Helen Lewis is an associate professor at University College Dublin School of Archaeology. Her background is in archaeology and anthropology (BA, University of Toronto), environmental archaeology (MSc, University of Sheffield) and archaeological soil micromorphology (PhD, University of Cambridge). She mostly works today on cave sites in Southeast Asia, but she still loves northwest European Neolithic and Bronze Age monuments and landscapes, and ancient agricultural soils.

Manuel Arroyo-Kalin is Associate Professor of Geoarchaeology at the Institute of Archaeology, UCL. He is interested in the Anthropocene, human niche construction and historical ecology, and uses earth science methods, including soil micromorphological analysis, to study past anthropic landscape modification and anthropogenic soil formation. His main research focus is the pre-Colonial human landscape history of tropical lowland South America, particularly the Amazon basin, where he is engaged in the long-term comparative study of Amazonian dark earths.

*Published by the McDonald Institute for Archaeological Research,
University of Cambridge, Downing Street, Cambridge, CB2 3ER, UK.*

The McDonald Institute for Archaeological Research exists to further research by Cambridge archaeologists and their collaborators into all aspects of the human past, across time and space. It supports archaeological fieldwork, archaeological science, material culture studies, and archaeological theory in an interdisciplinary framework. The Institute is committed to supporting new perspectives and ground-breaking research in archaeology and publishes peer-reviewed books of the highest quality across a range of subjects in the form of fieldwork monographs and thematic edited volumes.
